The Regional Operational Plan Series was established in 2012 to archive and provide public access to operational plans for fisheries projects of the Divisions of Commercial Fisheries and Sport Fish, as per joint-divisional Operational Planning Policy. Documents in this series are planning documents that may contain raw data, preliminary data analyses and results, and describe operational aspects of fisheries projects that may not actually be implemented. All documents in this series are subject to a technical review process and receive varying degrees of regional, divisional, and biometric approval, but do not generally receive editorial review. Results from the implementation of the operational plan described in this series may be subsequently finalized and published in a different department reporting series or in the formal literature. Please contact the author if you have any questions regarding the information provided in this plan. Regional Operational Plans are available on the Internet at: <http://www.adfg.alaska.gov/sf/publications/>

ABSTRACT

Coho *Oncorhynchus kisutch* smolt abundance and adult coho escapement will be estimated from the Taku River, above Canyon Island, near Juneau, Alaska using multiple, independent sampling approaches consisting of: coded wire tags implanted in smolt, adult harvest sampling, and an inriver adult mark-recapture experiment. A modified Petersen estimator will be used to estimate the smolt emigration in 2016-2018. Mark-recapture studies will be used to estimate inriver runs for adult coho salmon in 2016-2018. Inriver harvest will be accounted for in determining escapement estimates for coho salmon annually. Scale samples of coho salmon will be used for age analysis to estimate annual age compositions. Coho salmon smolt will be systematically sampled to estimate the mean length for each species.

Key words: coho salmon, adult production, smolt production, coded wire tag, Petersen estimator, marine survival, exploitation, mark-recapture, inriver run, escapement, total run, age composition, Taku River.

PURPOSE

This operational plan details procedures necessary for estimation of coho salmon smolt abundance in 2016-2018, and adult harvest in 2017-2019 gathered from the coded wire tag (CWT) program annually. This plan also details methods used for the estimation of adult coho escapement in 2016-2018 using information gathered from the adult sampling program. Stock identification programs provide stock specific harvests, from which total adult production, exploitation rates, harvest distribution and survival parameters are estimated. These data can be used to improve management planning and implementation for: 1) Alaska Department of Fish and Game (ADF&G) management, 2) terminal run management by the ADF&G and Department of Fisheries and Oceans Canada (DFO) and 3) coastwide management in the Pacific Salmon Commission (PSC) process. This project will aid both countries in following the management directive. Stock assessment parameters such as harvest, escapement, exploitation rate, smolt production, and brood year production will be directly estimated through implementation of the smolt tagging and adult escapement projects.

BACKGROUND

The Taku River (Figure 1) produces the largest runs of coho salmon *Oncorhynchus kisutch* and Chinook salmon *O. tshawytscha* in Southeast Alaska (SEAK) and north of the Skeena River in British Columbia (McPherson et al. 1998; Yanusz et al. 1999). From 1992 to 2015, the estimated total run of coho salmon originating from above Canyon Island has averaged 182,000 fish, and the recent 5-year average has been 136,000.

Detailed stock assessment projects designed to directly estimate parameters such as harvest, escapement, exploitation rate, smolt production, survival rates and brood year production have been in place since 1987 for coho salmon. This project is an ongoing cooperative programs between ADF&G and DFO in concert with the Taku River Tlingit First Nation (TRTFN). Coded wire tags were placed in coho salmon smolt captured in the mainstem Taku River beginning in 1991 (Elliott and Bernard 1994). This program was expanded to include Chinook salmon smolt in 1993 (McPherson et al. 2000), and since then both species have been marked with CWTs annually.

Figure 1.–The Taku River drainage of northwestern British Columbia and Southeast Alaska.

The Parties (i.e., U.S. and Canada) concurred on a new PST agreement in June 1999. Included in that agreement is a specific directive in Annex IV, Chapter 1 of the treaty stating that the Parties affirm their intent to develop and implement abundance-based management regimes for transboundary (i.e., Alsek, Stikine, and Taku rivers) Chinook, sockeye, and coho salmon.

PRIMARY OBJECTIVES

1. Estimate the number of coho salmon smolt (≥ 75 mm FL) leaving the Taku River that originated from above Canyon Island annually, such that the relative precision of the calculated 95% CI is $\leq 25\%$.
2. Estimate the escapement of adult coho salmon past Canyon Island annually between June and early October, such that the relative precision of the calculated 95% CI is $\leq 20\%$.
3. Estimate the age composition of adult coho salmon passing Canyon Island annually between June and early October, such that the absolute precision of the calculated 95% CIs are ≤ 6 percentage points.

SECONDARY OBJECTIVES

1. Estimate the marine harvest in sampled salmon fisheries of adult coho salmon that originated from above Canyon Island in the Taku River via recovery of CWTs annually, such that the relative precision of the calculated 95% CI is ≤ 30 .
2. Estimate the age composition of coho salmon smolt (≥ 75 mm FL) captured near Canyon Island annually such that the absolute precision of the calculated 95% CI is ≤ 9 percentage points.
3. Estimate the mean lengths of coho salmon smolt (≥ 75 mm FL) captured near Canyon Island annually such that the precision of the calculated 95% CI is ≤ 2 mm of the point estimate.
4. Estimate the mean weight of coho salmon smolt to the nearest 0.1 g annually such that the precision of the calculated 95% CI for the mean is ≤ 0.5 g of the point estimate.
5. Test the hypothesis that smaller coho salmon smolt (75–85 mm FL) survive at the same rate as larger smolt (> 85 mm) annually.

Calculation of the above parameters will allow us to also estimate total adult production, exploitation rates, and marine survival rates.

METHODS

STUDY DESIGN

Smolt Abundance

All methods described below will be similar for each year of the study (2016-2018).

Separate mark-recapture experiments will be used to estimate the abundance of coho salmon smolt emigrating from Taku River above Canyon Island (Figure 1). Smolt will be tagged with CWTs and marked with adipose fin clips as part of Event I of a two-event closed population mark-recapture experiment. As part of Event II, returning adult coho salmon will be inspected for a missing adipose fin.

Smolt trapping operations will be based out of a camp located just upstream of Canyon Island to implement the marking event (Figure 2). Approximately 150–300 minnow traps baited with salmon roe will be fished daily in the mainstem of the Taku River near Canyon Island beginning as soon as the river is open to boat and plane traffic, with a tentative startup date of mid-April each season. Three trap lines will be set between approximately 10 km above and below the upper camp. Each trap line will be maintained by 2 personnel and will consist of 50–100 traps per trap line. Smolt from all trap lines will be transported back to camp for processing each day. Seine nets will also be used along gravel bars on the Taku River mainstem by 3-person crews to capture coho salmon smolt to supplement minnow trap catches. When outmigration of smolt commences in early May, seining effort will increase accordingly. All healthy **coho smolt ≥ 75 mm FL** captured each day will be tranquilized with a buffered tricaine methanesulfonate (MS-222) solution, injected with a CWT, and have their adipose fin excised. Each CWT is formed by cutting a 1.1 mm section of wire from a spool stamped with a numeric code unique to each spool. Each spool contains enough wire for approximately 5,000, 10,000 or 20,000 tags. Two unique codes will be used each day for coho salmon in different size categories (75–85 mm FL; >85 mm FL), and spools will be changed only after they are completely used.

Adult coho salmon will be sampled as they return to the Taku River, each year 2016-2018. Each season adult coho salmon caught at Canyon Island in fish wheels and set gillnets, as well as in inriver test and commercial gillnet fisheries, will be inspected for missing adipose fins (June to early October). Personnel from the ADF&G Division of Sport Fish (SF) and Division of Commercial Fisheries (CF), DFO, and TRTFN Fisheries will sample these adults and record the associated data. The marked fraction (fish missing adipose fins) of coho salmon captured in the fish wheels and gillnets will be used to estimate smolt abundance.

SAMPLE SIZES – SMOLT ABUNDANCE

Sampling targets for coho salmon smolt are based on historical precedents. From 2006 - 2015, we have captured and tagged around 1.0% of the total smolt emigration. Production has averaged 1.8 million smolt per year over that time, and 1.0% of this average is 18,000 smolt. If we tag at least 18,000 fish and given an average marine survival rate of 9.9%, then to meet the precision criteria in primary objective 1 (half-width of the calculated 95% CI is $\leq 25\%$ of the point estimate) we will need to examine approximately 6,700 returning adults to estimate smolt abundance for the previous year (Robson and Regier 1964). On average 2,300 coho salmon have been inspected at Canyon Island and another 7,000 have been examined in the inriver test and Canadian commercial fishery. Given this, an expected total of over 9,000 coho salmon will be examined each year and objective statements regarding coho salmon smolt estimates will be met or exceeded.

Figure 2.—Location of central portion of study area on Taku River near Canyon Island, Southeast Alaska.

MODEL ASSUMPTIONS FOR ESTIMATION OF SMOLT ABUNDANCE

These two-event closed population mark-recapture experiments are designed so that a Petersen-type estimator may be used to estimate abundance. For the estimates of abundance to be unbiased, certain assumptions must be met (Seber 1982). These assumptions, expressed in the circumstances of this study, along with their respective design considerations and test procedures, are:

Assumption I: There Is No Recruitment to the Population Between Years

Considering the life histories of coho salmon, there should be no recruitment between sampling events. Because almost all surviving smolt return to their natal stream as adults to spawn, there will be no meaningful recruitment added to the population while they are at sea (i.e., low incidence of straying).

In regards to coho salmon, the population for which abundance is being estimated is smolt produced from stock that spawn above Canyon Island. Those fish from stocks that spawn downstream of Canyon Island should not be subject to capture either as smolt or adults. Approximately 22% of adult coho salmon fitted with radio tags in 1992 near the mouth of the Taku River spawned below Canyon Island (Eiler et al. 1993). Studies on the Taku River in previous years have shown some straying of fingerlings tagged above Canyon Island to tributaries downstream. Also, some adults tagged as smolt leaving tributaries downstream of Canyon Island have been caught in the fishery upstream of Canyon Island. However it is believed that the observed straying of smolt and adults past Canyon Island will be an insignificant source of potential bias when estimating abundance. Thus, it is assumed that tagged coho salmon smolt represent production from stocks that spawn above Canyon Island.

Assumption II: There Is No Trap-Induced Behavior

There is no explicit test for this assumption because the behavior of unhandled fish cannot be observed. Trap-induced behavior is unlikely because different sampling gears will be used to capture smolt and adults and results from other studies (Elliott and Sterritt 1990; Vincent-Lang 1993) indicate that clipping adipose fins and implanting CWTs does not affect the mortality of tagged salmon smolts.

Assumption III: Tagged Fish Will Not Lose Their Marks Between Sampling Events and All Marks Are Recognizable

The use of properly applied adipose fin clips will ensure that marks are not lost and that all marked fish are recognizable during second event sampling. Adipose fins will not regenerate like other fins if excised at the base. Naturally missing adipose fins on wild stocks of coho salmon are very rare (Magnus et al. 2006). All adipose fin clipped fish will be used estimating smolt abundance regardless of presence of valid CWT wire.

Assumption IV: One of the Following Three Sets of Conditions on Mortality and Sampling Will Be Met:

- S1) All fish have an equal probability of being captured and marked during the first event; or
- S2) Complete mixing of marked and unmarked fish occurs prior to the second event, hence all fish have the same probability of surviving between events across all tagging groups ;
or

- S3) All fish have an equal probability of being captured and inspected for marks during the second event, hence all fish have the same probability of surviving between events across all tagging groups

Regarding S1 for the smolt to adult mark recapture:

Both minnow traps and beach seines are used to capture smolt. Minnow traps can be size-selective, however about half of the coho sampled are caught in beach seines which are not size-selective.

Coho salmon smolt represent at least 2 age groups and cover a range of sizes. In the past there has been size-selective sampling during the first event for coho salmon emigrating from the Taku River (Appendix A1; Jones et al. 2006), but the more recent use of beach seines should mitigate the effects of size-selectivity,

Regarding S2 for the smolt to adult mark recapture:

Due to the extended time period between the marking and recovery events and behavior of salmon between these events, it is believed that complete mixing of marked and unmarked fish occurs prior to the adult recovery events in the lower river. If the migratory timing of smolts and adults from a particular spawning area are related then this assumption may not be met. For coho size-selective mortality rates have occurred in the past (Jones et al. 2006). If this is true then this assumption will not be met.

Regarding S3 for the smolt to adult mark recapture:

Adult coho salmon immigrations will be sampled almost continuously with fish wheels and gillnets. These methods promote equal probabilities of capture through migrations and, at a minimum, ensure that no segments of the adult immigrations have zero probability of capture during the second event. For coho salmon, size-selective mortality rates have occurred in the past. (Jones et al. 2006). If this is true then this assumption will not be met.

For coho salmon, if there is unequal survival between tagging groups none of the three sets of conditions will be satisfied. Equal survival between the coho salmon smolt tagging groups (2 sizes) will be evaluated using contingency table analysis to test for lack of independence between tagging group and adult tag recovery rate during adult sampling (secondary objective 2). If no lack of independence between tagging group and adult tag recovery is detected, at least S2 may be satisfied and Chapman's (1951) modification to the Petersen estimator will be used to estimate abundance after pooling the tag codes. If lack of independence is detected between adult tag recovery rate and tagging group, equal probability of capture during the tagging event will need to be evaluated. The catchability coefficient (\hat{A}) for larger to smaller smolt (equation 6; page 14) will be estimated. If the estimate of A is not significantly different from 1.0, Chapman's (1951) formula will be used to estimate abundance as described above. Otherwise, the modified estimator (equation 4; page 13) will be used to provide an unbiased estimate (see Data Analysis; Appendix A1). Past use of this estimator has increased the coefficient of variation of the estimate modestly (about 2.5 percentage points).

AGE COMPOSITION AND MEAN LENGTH AND WEIGHT OF COHO SALMON SMOLT

A systematically drawn sample of 1% of the captured coho salmon smolt ≥ 75 mm FL will be collected, which should exceed minimum sample sizes needed to meet criteria for secondary objectives 2, 3, and 4. Only coho salmon smolt ≥ 75 mm FL will be considered for sampling as smaller fish are more difficult to handle and have a higher probability of remaining in the river for subsequent years. A sample of 132 is sufficient to meet criteria for estimating the proportions in the age composition assuming that the worse case scenario that the two fresh water ages are both occur about 50% of the time, and data loss occurs 10% of the time. (Thompson 2002). When estimating mean length of coho smolt, if the standard deviation of fork length in the population is ≤ 12.2 mm (the maximum standard deviation observed in 2013-2015), 143 samples are required $([(1.96)(12.2)/2])^2 = 142.9$ to be within 2 mm (Thompson 2002, p. 36). Similarly when estimating mean weight of coho smolt, if the standard deviation of the weight in the population is ≤ 3.2 g (the maximum standard deviation observed in 2013-2015), 158 samples are required $([(1.96)(3.2)/.5])^2 = 157.4$.

Based on an expected catch of about 18,000 coho salmon smolt, scale samples, length, and weight measurements need to be taken from every 100th coho salmon smolt to achieve a systematic sample of 180.

HARVEST OF COHO SALMON

Recovery of tagged and marked adults in the various fisheries will be used to estimate harvest of coho salmon (originating above Canyon Island) in marine fisheries each year. To meet the criteria in secondary objective 1 (95% relative precision (RP) = $\pm 30\%$), approximately 18,000 coho salmon smolt need to be tagged each year according to procedures in Bernard et al. (1998). This is based on inspecting at least 20% of the anticipated harvest in the various commercial and sport fisheries (Anne Reynolds, fishery biologist, ADF&G-CF, Douglas, personal communication 2015; Mike Jaenicke, fishery biologist, ADF&G-SF, Douglas, personal communication 2014).

Using harvest data (Appendix A2) from 2014 to show that objective criteria can likely be met with 18,000 smolts being tagged. Assuming 926,000 coho salmon smolt outmigrate each year, we anticipate 65 random fishery recoveries of CWTs annually.

COHO SALMON ESCAPEMENT AND AGE COMPOSITION AT CANYON ISLAND

All groups will cooperatively conduct a mark-recapture experiment to estimate the number of adult coho salmon returning past Canyon Island between mid-June and early October each year. Personnel of ADF&G and TRTFN will capture coho salmon in two fish wheels at Canyon Island, where one wheel is positioned on each bank of the river. The wheels will be operated continuously and a aluminum 2-basket design has been implemented to enable fish wheels to turn during periods of low flows, which occur in late fall. See Kelley et al. (1997) and Kelley and Milligan (1997) for project details. If fish wheels are inoperative for more than 2 consecutive days, gillnets (12 ft x 100 ft, 5 1/8 in mesh) will be used to capture coho salmon at Canyon Island during the hiatus. Coho salmon will be carefully removed from the fish wheels or gillnets and placed into a trough filled with water. All healthy coho salmon ≥ 350 mm MEF caught in either fish wheels or gillnets will be measured, examined to determine sex, inspected for missing adipose fins, and tagged with a length of plastic “spaghetti” tubing imprinted with an individual

number sewn through the dorsal musculature just below the posterior portion of the dorsal fin. Some fish will also be sampled for scales if they meet the criteria below. All fish will be released at the site of capture. Past studies on coho salmon have shown that the loss of spaghetti tags between the marking site at Canyon Island and the recapture area located just upriver above the border is rare, so no secondary mark will be added to tagged fish. Additionally, the loss of the primary spaghetti tag has been viewed as inconsequential as fish are normally recovered within 3 weeks of tagging and tagging scars are still visible and serve as a secondary mark (Yanusz et al. 1999). Recovery of tags from the commercial fishery is through return by fishermen (a condition of each fishing permit) and past studies have shown that all tags are likely returned (Kelley et al. 1997). A \$5 (Canadian) reward for each recovered tag will be paid by DFO as additional incentive to report tags. Operation of the fish wheels or gillnets will end in early October or when daily catches have dwindled to near zero.

SAMPLE SIZES – ADULT ESCAPEMENT

The recent 10-year average (2006-2015) Taku River coho salmon smolt emigration is 1.8 million. Applying the 10-year average (2006-2015) marine survival of 9.9% to the total outmigration of 1.8 million smolt results in a total run of about 180,000 fish. Assuming this total run forecast is accurate based on the past 10 years of data, and applying an average U.S. marine exploitation rate of 38%, then about 110,000 adult coho salmon should pass Canyon Island each year. From 2006-2015, the fish wheels have caught about 2.1% of the coho salmon that pass Canyon Island. Thus, we predict about 2,300 adult coho salmon will be marked with spaghetti tags and released at Canyon Island each year. In order to meet primary objective 2 criteria (i.e., the half-width of the calculated 95% CI is $\leq 20\%$ of the point estimate), 3,281 adult coho salmon must be inspected upriver in the test and Canadian commercial fisheries as part of Event II (Robson and Regier 1964). Over 11,000 coho salmon have been harvested on average each year (2006-2015) upriver in the test and Canadian commercial fisheries, which is an ample sample in Event II to meet the objective criteria provided all assumptions hold.

Based on a population of 110,000 and a scale regeneration rate (data loss) of 20%, a systematically drawn sample of 443 adults must be sampled using procedures in Thompson (1987) to satisfy the precision criteria of primary objective 3, (that the half-width of the calculated 95% CIs are ≤ 6 percentage points of the point estimates). If at least 2,300 fish are captured at Canyon Island, then every 4th coho salmon caught will need to be sampled for scales. The estimates should be unbiased even if the sampling gear is size selective; the differences in age composition for Taku River coho salmon almost entirely reflect differences in freshwater age, and there is no relationship between freshwater age and the size of adult coho salmon. Personnel from DFO will sample fish for tags, age, and size in the inriver test and Canadian commercial fisheries from June into early October. Scales will be taken from the preferred area (i.e., the left side of the fish; 2 rows up from the lateral line on an imaginary line from the posterior insertion of the dorsal fin to the anterior insertion of the anal fin; Scarnecchia 1979). Four scales will be taken from each fish and mounted on gum cards for later impression into acetate cards using a scale press. Ages will be determined from patterns of circuli according to protocols in Mosher (1968) and the CF scale-aging group.

MODEL ASSUMPTIONS FOR ESTIMATION OF COHO SALMON ESCAPEMENT

This two-event closed population mark-recapture experiment is designed so that a Petersen-type estimator may be used to estimate abundance. For the estimate of abundance to be unbiased, certain assumptions must be met (Seber 1982). These assumptions, expressed in the circumstances of this study, along with their respective design considerations and test procedures, are:

Assumption I: The Population Is Closed to Births, Deaths, Immigration and Emigration

Considering the short distance between Canyon Island and the inriver fisheries just upstream, and considering the life history of the species, there should be no recruitment between sampling events. First event sampling (marking) will begin prior to any significant passage of fish past the tagging sites and will continue through the run until passage has dropped to near zero.

Assumption II: There Is No Trap-Induced Behavior

There is no explicit test for this assumption because the behavior of unhandled fish cannot be observed. There should be no trap-induced behavior because different sampling gears are used in different sampling events. However, we will attempt to meet this assumption by minimizing holding and handling time of all captured fish. Any obviously stressed or injured fish will not be tagged.

Assumption III: Tagged Fish Will Not Lose Their Marks Between Sampling Events and All Marks are Recognizable

Past studies on coho salmon have shown that the loss of spaghetti tags between the marking site at Canyon Island and the recapture area located just upriver above the border is rare, so no secondary mark will be added to tagged fish. Additionally, the loss of the primary spaghetti tag has been viewed as inconsequential as fish are normally recovered within 3 weeks of tagging so tagging scars will serve as a secondary mark.

Assumption IV: One of the Following Three Conditions Will Be Met

1. All coho salmon will have the same probability of being caught in the first event, or
2. All coho salmon will have the same probability of being captured in the second event; or,
3. Marked fish will mix completely with unmarked fish between samples.

In this experiment, it is unlikely that marked and unmarked fish will mix completely. Fish wheels will be operated continuously during the run. However, experience has shown that probabilities of capture of coho salmon change as their annual migration progresses. Fluctuations in water levels at Canyon Island can affect the efficiency of fish wheels and gillnets (Yanusz et al. 1999). Also, the change from the commercial fishery to a test fishery halfway through the migration affects the probabilities of capture during Event II, although in some years most of the sample is derived from the test fishery.

Equal probability of capture will be evaluated by time, area, size, and sex. The procedures to analyze sex and length data for statistical bias due to gear selectivity are described in Appendix A3. If different probabilities are indicated, abundance estimates will be stratified within size groups.

To further evaluate the three conditions of this assumption, contingency table analyses recommended by Seber (1982) and described in Appendix A4 will be used to detect significant

temporal or geographic violations of assumptions of equal probability of capture. Based on previous experience, it is anticipated temporal violations of these assumptions will be detected, and a Petersen-type model would yield a biased estimate. Therefore, abundance will most likely be estimated according to models developed by Darroch (1961) for a two-event mark-recapture experiment on a closed population when temporal or spatial distributions of fish affect their probabilities of capture.

DATA COLLECTION

All healthy coho salmon smolt ≥ 75 mm FL captured near Canyon Island without marks will be tranquilized with a buffered MS-222 solution, tagged with a CWT following procedures described in Koerner (1977), given an adipose fin clip, and then released. Note that all tagged fish will be held overnight to test for post-tagging mortality and a portion will be tested for tag retention. Any smolt captured possessing an adipose fin clip prior to tagging will be tested for the presence or absence of a CWT (i.e., passed through a magnetic tag detector) and recorded as positive or negative.

Codes used will be recorded on the **CODED WIRE VERIFICATION FORM** (Appendix B1) obtained from the CF Mark, Tag, and Age Laboratory (CF Tag Lab); a short section of each spool of coded wire will be taped to the form the first day of tagging with a new tag code. All tag and recapture data will be recorded daily on the form entitled **CWT DAILY TAGGING FORM** (Appendix B2). Environmental conditions will be recorded daily on the form entitled **DAILY ENVIRONMENTAL CONDITIONS FORM** (Appendix B3). A new **CWT DAILY TAGGING FORM** will be filled out for each day of operation. Daily procedures will be as follows:

1. Record location, date, and species.
2. Record water and air temperature (Min-Max) to nearest 1°C, water depth. Data should be collected at 0800 hours each day.
3. At 0800–0830 hours mix the fish in the holding net pen, then net and check 100 fish from each holding pen for tag retention and record this information on the **CWT DAILY TAGGING FORM**. If tag retention is 98/100 or greater, empty the net pen of all smolt making sure to count and record all mortalities. Next, transport the smolt to the release site and release all fish. If tag retention is less than 98/100, reprocess the entire batch of smolt in the net pen and retag any that test negative for CWTs. Examine any mortalities for proper tag placement and adjust the head mold if necessary. Check the position of the bevel on the needle and the sharpness of the needle. Reposition, sharpen, or replace the needle if necessary.
4. Check the minnow trap lines and transport all fish to camp for processing. Salmon smolt will be sorted by species and also by size for coho salmon (75–85 mm FL; >85 mm FL). Inspect each live fish and count the number possessing adipose fin clips; record the number of fish with adipose fin clips under "Recaptures" on the **CWT DAILY TAGGING FORM**. Test all recaptures for tag retention. Record results of tag retention on the **CWT DAILY TAGGING FORM**.
5. For all unmarked fish, apply a CWT and test for a positive reading using a tag detector. If rejected by the detector, retag. Keep an accurate tally of all retags on a hand counter. Write

the beginning and ending machine numbers on the form and record retags, mistags, and practice tags. Show your calculations for the number of tags used for each tag code daily.

6. Systematically select every 75th coho salmon from combined catches and measure FL to the nearest whole millimeter, weigh to nearest 0.1 g, collect scales, and record date, length and weight. Record the total number of coho salmon recaptured.

ADF&G CWT ONLINE RELEASE maintained by the CF Tag Lab will be filled out after at the end of the tagging season. Information in this database will be used to estimate the number of smolt retaining CWTs. A 5 cm length of coded-wire will be attached to the **CODED WIRE VERIFICATION FORM** to verify the tag codes. If one roll of coded wire is depleted during a tagging session, a new **CWT DAILY TAGGING FORM** will be filled out, and a piece of wire from the new spool will be attached to the **CODED WIRE VERIFICATION FORM**.

For coho salmon smolt sampled for length, weight, and scales, 12–15 scales will be removed from the preferred area (Scarnecchia 1979) on the left side of the fish. Scales from up to four fish will be sandwiched between two 1 in x 3 in microscope slides, and the slides will be taped together with frosted scotch tape. The length of each fish will be written in the corners of the tape portion that correspond to the location of individual fish scales on each slide (Figure 3). Location, species, and date will also be recorded on each slide. Length and weight data for each fish will be recorded on a **SALMON SMOLT LENGTH, WEIGHT, AND SCALE SAMPLES** form (Appendix B4). Additional criteria includes:

- 1) Do not tape over any scales;
- 2) Make sure scales are put in the designated area for each fish;
- 3) Always number each slide at its top;
- 4) Always record the initials of the sampler under the slide number; and
- 5) Clean the scales and spread them out so that they are separated and align them as shown in Figure 3.

For sampling adult salmon, river stage, water temperature, fish wheel RPM, the hours of fish wheel operation (each fish wheel), and hours of gillnet fishing time will be recorded daily on a **FISHING EFFORT FORM** (Appendix B5). Fish wheel catches will be checked two or more times daily, and the numbers of fish caught and tagged will be recorded on a **WHEEL SAMPLING PERIOD FORM** (Appendix B6). When the fish wheels are not operational, gillnets will be fished about 6 hours per day and catches will also be recorded on the **WHEEL SAMPLING PERIOD FORM**. For coho salmon, each spaghetti tag number released, date released, fish length, and sex will be recorded on **MARK-SENSE** forms (ADFG 1996¹; available from Mike Jaenicke, fisheries biologist, ADF&G-SF, Douglas). Dates and tag numbers of adult coho salmon released with spaghetti tags will be relayed daily to the SF project biologist. During spaghetti tag recovery in Canada, commercial or test fishing effort (boats and days open), total catch, fish examined, lengths of fish examined, and individual tag numbers recovered will be relayed weekly by the

¹ ADFG (Alaska Department of Fish and Game). *Unpublished*. Length, sex, and scale sampling procedure for sampling using the ADF&G adult salmon age-length mark-sense form version 3.0, Alaska Department of Fish and Game, Region I, Commercial Fisheries, June 1996.

DFO project biologist to the SF project biologist. When fish wheels are operating marginally, then gillnets will be fished about four hours per day.

Figure 3.—Preferred microscope slide layout for coho salmon smolt scale samples.

Completion of smolt population and harvest estimates requires sampling coho salmon escapement for CWTs in succeeding years. All of the coho salmon escapement sampling will be done at Canyon Island using fish wheels and gillnets. A **HATCHERY RACK AND ESCAPEMENT SURVEY FORM** (Appendix B7) provided by the CF Tag Lab will be completed for each sample day (fish wheel or gillnet) to document the number of fish examined and the number of fish possessing adipose fin clips. Scale samples, length, and sex will be taken from every third coho salmon examined. Heads will be taken from all adult coho salmon that possess adipose fin clips, and a uniquely-numbered cinch strap will be attached to each head. Capture site, date, gear, fish sex and length (MEF), clip quality, and sample and head number (i.e., cinch strap number) will be recorded on the **HATCHERY RACK AND ESCAPEMENT SURVEY FORM**.

A scale sample will also be taken from every adult coho salmon possessing adipose fin clips, as described above, and cross-referenced to the sample data using the cinch strap number. Each head and associated data will be shipped to Juneau in specially labeled coolers on the next available flight. The Douglas office will be notified prior to each head shipment, and Douglas staff will transport the heads and associated data forms to the CF Tag Lab.

DATA REDUCTION

The field crew leader will record and error-check all data. Data forms will be kept up to date at all times. Data will be sent to the Douglas office at regular intervals and inspected for accuracy and compliance with sampling procedures. Data will be transferred from field notebooks or forms into Microsoft Excel™² spreadsheet files. When input is complete, data lists will be obtained and checked against the original field data.

² This and subsequent product names are included for a complete description of the process and do not constitute product endorsement.

Electronic data files will be used to check tagging totals with field notebooks, to identify lengths less than prescribed guidelines, sampling rates for age and length, and for data on the **CWT DAILY TAGGING** and **HATCHERY RACK AND ESCAPEMENT SURVEY FORMS**. Completed **CODED WIRE VERIFICATION** and **HATCHERY RACK AND ESCAPEMENT SURVEY FORMS** will be sent to the CF Tag Lab in Juneau where all CWT information for ADF&G statewide is compiled and stored. Each year Alaskan CWT data are shared with the Pacific States Marine Fisheries Commission who maintains a permanent and standardized coastwide CWT database.

Adult salmon catches, numbers tagged, and those possessing adipose fin clips will be tabulated daily by species. The number of adult salmon, length, and scale samples will be compared to the fish wheel and gillnet catches to determine if sampling protocol was followed. Spaghetti tag numbers and release dates will be compared against recoveries to locate and resolve nonsensical values. Spaghetti tag releases and recoveries will be tabulated by statistical week.

When the reports are completed, electronic copies of the data will be sent to ADF&G-SF Research and Technical Services (RTS) in Anchorage for archiving, along with a data map. Smolt data (date, age, length and weight) will be provided. All other data (CWT tag and release, adult CWT, adult age-sex-length) will be formatted and transferred to SF or CF permanent databases in Region I, ADF&G.

DATA ANALYSIS

Smolt Abundance

The mark-recapture experiment based on coho salmon smolts and returning adults was designed to use Chapman's modification of the Petersen Method (Seber 1982) to estimate abundance of smolt each year. If diagnostic tests indicate that necessary assumptions for unbiased estimation are satisfied, the Chapman (1951) model will be used to estimate abundance. Variance will be estimated using bootstrapping techniques similar to what is described below for a Chapman model for estimating adult coho abundance.

If the null hypothesis of independence is rejected between adult tag recovery rate and tagging group, and between sampling events and occurrence of freshwater age of fish at smolting from the Taku River, a weighted variant of Chapman's modification to the Petersen estimator will be used to estimate abundance:

$$\hat{S}_{co} = \frac{(\hat{A}M_1 + M_2 + 1)(C + 1)}{\hat{A}(R_1 + \hat{\pi}R_3) + R_2 + (1 - \hat{\pi})R_3 + 1} - 1 \quad (4)$$

where M_i is the number of smolts marked by size group (1 = 75–85 mm FL, 2 = >85 mm FL) in year X, C the number of adults in year X+1 inspected for marks, R_i the subset of C with marks representing a size group of smolts (3 = group unknown), A is the ratio of the catchability coefficients for larger (>85 mm FL) to smaller (\leq 85 mm FL) smolt in year X, and π is the fraction of adults in year X+1 that were smolts 75–85 mm FL in year X. The estimate A is used to adjust for differences in catchability in year X such that $A > 1$ when larger smolt are more

catchable, and <1 when larger smolt are less catchable. Because some recaptured fish are not sacrificed to find tags or some marked adults do not contain tags, π is used to assign recaptured fish of unknown pedigree to the appropriate smolt size group. An estimate of π is:

$$\hat{\pi} = \frac{T_1}{T_1 + T_2} \quad (5)$$

where T_i is the number of all tags representing a smolt size group recovered or recaptured from adult salmon regardless of how or where recovered or recaptured.

Evidence for smolts not having equal probability of being marked regardless of size can be found through calculations based on estimates of relative freshwater age composition of smolts and adults. If \hat{p} is the estimated fraction of all adults that are of age 1-freshwater, if $\hat{\phi}_1$ is the estimated fraction of smolts in the smaller-size group that were age 1-freshwater, and if $\hat{\phi}_2$ is the estimated fraction of smolts in the larger-size group that were age 1-freshwater, an estimate of the ratio of catchability coefficients for larger to smaller smolt is (see Appendix Addendum A1.1 in Appendix A1 for derivation):

$$\hat{A} = \frac{T_2(\hat{\phi}_2 - \hat{p})}{T_1(\hat{p} - \hat{\phi}_1)} \quad (6)$$

An estimate of the sampling variance of \hat{A} will be obtained through bootstrapping (Efron and Tibshirani 1993). Bootstrap replicates of T_1 and T_2 will be obtained using the multinomial model described in Appendix A1, and bootstrap replicates of \hat{p} , $\hat{\phi}_1$, and $\hat{\phi}_2$ will be obtained using 3 independent binomial models based on the sample statistics used to estimate these three parameters. Equation 6 will be used to calculate a large number of bootstrap samples of \hat{A} and a formula similar to equation 3 will be used to estimate the sampling variance of \hat{A} .

A description of the application of equations 4–6 is provided in Appendix A1, as well as a description of the bootstrap procedures used to estimate variance.

Harvest

Methods described in Bernard and Clark (1996, their Table 2) will be used to estimate the marine harvest of coho salmon from the Taku River annually using a stratified catch sampling program of marine commercial and sport fisheries. Commercial catch data for the analysis will be summarized by ADF&G statistical week and district (for gillnet and seine fisheries), or by period and quadrant for troll fisheries (similar to Clark et al. 1985).

Sport harvest estimates from ADF&G Statewide Harvest Survey reports (e.g., Jennings et al. 2011) will be apportioned using information from sampled marine sport fisheries to obtain estimates of total harvest by biweek and fishery. Sport fish CWT recovery data will be obtained from CF Tag Lab reports and summarized by biweek and fishery (e.g., biweek 16 during the Sitka Marine Creel

Survey) to estimate contribution. In most cases, CWTs of interest may be recovered in only a few of the sport fish sampling strata that defined the fishery biweek. Assuming that the harvests of fish with CWTs of interest are independent of sampling strata within fishery biweeks, harvests and sampling information will be totaled over the fishery biweek to estimate contributions.

The estimates will be based on the:

- 1) The fraction of the cohort marked;
- 2) number of coho salmon harvested;
- 3) fraction of the harvest inspected for the presence of adipose fin clips;
- 4) number of coho salmon in the sample possessing adipose fin clips;
- 5) number of sacrificed fish whose heads reached the CF Tag Lab;
- 6) number of these heads that contained coded wire;
- 7) number of these valid, legible coded wire that were decodable; and
- 8) number of decodable tags of the appropriate code (i.e., originally released in the Taku River).

Abundance of Adult Coho Salmon

A two-sample mark-recapture model will be used to estimate the number of adult coho salmon passing by Canyon Island. The appropriate abundance estimator will depend on the results of the aforementioned tests. If stratification is not needed, Chapman's (1951) version of Petersen's abundance estimator for closed populations (see Seber 1982) will be used:

$$\hat{N} = \frac{(n_1 + 1)(n_2 + 1)}{(m_2 + 1)} - 1 \quad (7)$$

where \hat{N} = estimated number coho salmon, n_1 = number of marked coho salmon moving upstream of Canyon Island, n_2 = number of coho salmon inspected for marks in the Canadian commercial and test fisheries, and m_2 = number of marked coho salmon recaptured in the Canadian commercial and test fisheries.

If temporal-geographic stratification is not required but stratification by size or sex is (see Appendix A3), estimates for each stratum will be generated using equation (7) and these estimates summed to estimate total abundance and variance.

An estimate of the variance for \hat{N} will be obtained through bootstrapping (Efron and Tibshirani 1993) according to methods in Buckland and Garthwaite (1991). The fate of the estimated \hat{N} in the experiment will be divided into capture histories (similar to those described in Table 1 above) to form an empirical probability distribution (*epd*). A bootstrap sample of \hat{N} will be drawn from the *epd* with replacement. From the resulting collection of re-sampled capture histories, n_1^* , n_2^* , m_2^* , and \hat{N}^* will be calculated. A large number (B) of bootstrap samples will be so drawn. The approximate variance will be calculated as:

$$\text{var}(\hat{N}) = \frac{\sum_{b=1}^B (\hat{N}_b^* - \hat{N}^*)^2}{B-1} \quad (8)$$

where \hat{N}^* is the average of the \hat{N}_b^* .

If geographic or temporal stratification is required, estimation of abundance will follow procedures described by Darroch (1961) using the computer program SPAS (Arnason et al. 1996). If stratification by size is required, size stratification will be conducted first and methods to correct for geographic or temporal capture heterogeneity will be applied independently to each size stratum. The contingency tables described in Appendix A4 will be further analyzed to identify: a) Event I strata (individual or contiguous groupings of temporal-geographic categories) where probability of recapture during the second event is homogeneous within strata and different between strata; and b) Event II strata where marked:unmarked ratios are homogeneous within strata and different between strata. Temporal categories generally will consist of groupings of sample data collected by week. Stratification will also be guided by environmental conditions encountered during data collection (river stage height and rainfall) and by previous experience gained when conducting mark-recapture experiments on this system. If the initial stratification does not result in an admissible maximum-likelihood (ML) estimate of abundance, further stratification may be necessary before an admissible estimate can be calculated. Nonadmissible estimates include failure of convergence of the ML algorithm in SPAS or convergence to estimators with estimated negative capture probabilities or estimated negative abundance within stratum. Goals in this case are always that observations within the pooled stratum should be as homogeneous as possible with respect to capture, migration, and recapture (Arnason et al. 1996).

A goodness of fit (GOF) test (provided in SPAS) comparing the observed and predicted statistics will indicate the adequacy of a stratified model. Once a stratification is identified that results in an admissible estimate of abundance, GOF will be evaluated. Further stratification, according to the guidelines described above, may be necessary to produce a model and abundance estimate with a satisfactory GOF. In general, the model selected will be that which provides an admissible estimate of abundance where no stratification guidelines are violated, no significant evidence of lack of fit is detected, and the smallest number of strata parameters are estimated for the model. This model will usually yield the smallest ML estimate of variance for the abundance estimate.

If the Darroch (1961) procedure is used to estimate abundance and the number of first and second event strata is not equal, the ML estimate of variance provided by the SPAS software will be used. If the number of first and second event strata is equal for the selected model, bootstrap methodology (Buckland and Garthwaite 1991) will be used to estimate variance and confidence intervals. There will be $(s)(t)$ capture histories for recaptured coho salmon, s capture histories for coho salmon marked but never recaptured, t histories for coho salmon captured upstream in the inriver fisheries without marks, and 1 history for all salmon never caught. These histories form a multinomial distribution with $(s+1)(t+1)$ cells. The frequency in these cells will sum to \hat{N} . A sample will be drawn from this multinomial distribution with replacement, and from this sample, equation 7 will be used to calculate a new estimate, \hat{N}^* , from the new sample. This process is

repeated a large number of times, say B times, to produce an estimated empirical frequency distribution \hat{F}^* for \hat{N} . The approximate variance for \hat{N} is calculated as described in equation 8.

Darroch developed his model without a correction for bias caused by the substitution of statistics in the model. This bias can be large when sample sizes are small. The difference between \hat{N} and \bar{N}^* is a measure of this bias. Also, \hat{F}^* will be used to develop approximate confidence intervals for \hat{N} ; either the percentile or BC_a methods of Efron and Tibshirani (1993) will be used to develop these confidence intervals.

The estimated escapement is the difference between the estimated passage by Canyon Island (result of equation 7 or the Darroch model) and the inriver harvest above Canyon Island (tallies from the commercial and test fisheries in Canada). If it is assumed the inriver harvest is known without error, the estimated variance for spawning escapement will be the same as the variance estimated for the passage by Canyon Island.

Age and Sex Composition

Proportions by age, sex or combination thereof of adult coho salmon and proportions by age for coho salmon smolt will be estimated by:

$$\hat{p}_j = \frac{n_j}{n} \quad (9)$$

and the associated variance approximated by:

$$\hat{var}[\hat{p}_j] = \frac{\hat{p}_j(1 - \hat{p}_j)}{n - 1} \quad (10)$$

where: p_j = the proportion in the population in group j ;

n_j = the number in the sample of group j ; and

n = the sample size.

Systematic selection of samples will promote proportional sampling and reduce bias from any inseason changes in age composition. For coho salmon smolts, statistics will be germane only to those fish captured. For adult coho salmon, statistics will be for the population. Because there is little (if any) relationship between size of adult and its freshwater age, no adjustment for any size-selective sampling should be necessary.

Testing the Hypothesis of Equal Survival Rates for Coho Salmon Smolts

All tags recovered from adults will be segregated by code into two groups corresponding to “smaller” and to “larger” smolts. The phrase “all tags” means all random and select tags recovered or voluntarily returned from marine fisheries and all tags recovered from Canyon Island and from freshwater commercial and test fisheries. From the sampling scenarios described above, we expect

to recover about 66 tags. In past years, about half the smolts tagged were “smaller” smolt and half “larger”. Assuming the same circumstances, approximately 9,000 “smaller” and 9,000 “larger” smolts should be tagged. About 33 (half) of the recoveries would be in each group under the null hypothesis of equal recovery rates. This expectation is based on there being no relationship between size of smolt and subsequent size of adult, which has proven to be the case with coho salmon. Without this smolt-to-adult link to size, there is no reason to believe that the probability of catching or sampling an adult is related to size as a smolt.

Power of the test will be investigated with simulation. If p_s and p_l are the expected recovery rates for each group of fish, $p_s = p_l$ under the null hypothesis, and 33 tags would be recovered for each group as per scenarios described above. To represent alternative hypotheses, numbers of recovered tags will be changed by ϕ as per $33 - \phi$ for “smaller” fish and $33 + \phi$ for “larger” such that $p_s = (33 - \phi)/9,000$ and $p_l = (33 + \phi)/9,000$. In the simulation a thousand pairs of random numbers of recovered tags will be drawn with the first of each pair from the binomial distribution $\text{binom}(9,000; p_s)$ and the second from $\text{binom}(9,000; p_l)$. A χ^2 value will be calculated for each pair and compared against the tabular value for this statistic when $\alpha = 0.05$. The number of pairs for which the calculated value is greater than the tabular correspond to the power of the test to detect a difference of $2\phi/(33+\phi)$ in the recovery rates solely due to differences in survival rates for the two groups. The value of ϕ will be altered and the simulation repeated for each alteration to find a meaningful difference that could be detected in recovery rates with reasonable power. By meaningful difference, we mean a difference large enough to cause the discrepancy observed between freshwater age compositions as smolt and adults.

A similar χ^2 test will be repeated on data once collected. If the null hypothesis is not rejected, there is no evidence that the estimated abundance would be biased from a combination of size-related differences in the capture and in the survival of smolt. However, given that freshwater age composition differs significantly between smolt and adult estimates, failure to reject the null hypothesis of equal recovery (survival) rates indicates that sampling of smolt is size-selective. The most likely reason for such sampling would be that larger, older smolts migrate after spring sampling has concluded. If the null hypothesis is rejected, the detected difference will be compared to the change in estimated age compositions to see if different survival rates could be the sole explanation.

SCHEDULES AND DELIVERABLES

OPERATIONS

Field activities for tagging coho salmon smolt near Canyon Island will begin inriver approximately mid-April and extend into early June each year, 2016-2018. Adult coho salmon tagging will begin in mid-June and continue into early October, each year 2016-2018.

REPORTS

A draft report will be written by the lead author and distributed to other authors for input by May 1 following each sample year. The final report will be submitted for final peer review by July 1 of each year. This report will be coauthored by the principal investigators from ADF&G and the project biometrician. The report will be published in the ADF&G, DSF Fishery Data Series as

well as the PSC Technical report series. The final report and all associated data will be provided to ADF&G DSF Research and Technical Services (RTS), Anchorage, and DFO Whitehorse for archiving purposes.

Project results will also be summarized in the annual report of the Joint Transboundary Technical Committee, a committee established by the PST to oversee the management of transboundary salmon stocks.

RESPONSIBILITIES

Jeff Williams, FB II, Project Leader (ADF&G-SF smolt and adult escapement). Works with Ed Jones (ADF&G) on field operations, data analysis, and report writing. Supervises smolt and adult coho salmon projects; edits, analyzes, and reports data; assists with field work; maintains near-daily email or telephone contact with field camps; arranges logistics with field crew and expeditor. Writes smolt and adult coho salmon sampling section of operational plan, assures that it is followed or modified appropriately with consultation with Jones and Power. Is coauthor on final report with Jones and Power.

Ed Jones, Fish and Game Coordinator, Project Leader (ADF&G-SF smolt and adult escapement). Works with Jeff Williams to set up all major aspects of adult Chinook salmon project, including planning, budget, sample design, permits, equipment, personnel, and training. Reviews operational plan. Is coauthor on final report with Williams and Power.

Sarah Power, Biometrician. Provides input to, edits, analyses, and approves sampling design. Coauthors operational plans and provides biometric details, including any changes or statistical techniques needed to provide precise and unbiased estimates for this project. Writes computer code and completes data analysis as necessary. Coauthors final report.

Nathan Frost, FWT III. This position serves as crew leader of the smolt camp tagging operations for juvenile Chinook and coho salmon, and collection and recording of all associated biological and catch-effort data with consultation from Williams. Ensures that the operational plan is followed to the extent possible, and implements inseason changes as authorized. Determines work schedules and assigns tasks to smolt crew members with Williams. Performs tagging and sampling summaries, and error-checks CWT tagging data daily. Monitors crew performance and corrects or trains the crew as needed. Performs maintenance on all sampling and camp equipment. Ensures pertinent portions of State SOP, such as safety and time reporting, are followed. Maintains near-daily contact with Williams for safety, data, and logistical needs.

Lee Close, FWT III. Will be in charge of running one of the trap lines and adjusting trap placements accordingly to maximize catches. Is responsible for daily operation and cleaning of the Mark IV coded wire tagging machines associated with smolt tag and release operations. Will measure Chinook smolt and record lengths and weights in a Rite-in-the-Rain® book. Works closely with crew leader to follow protocol and quality control while maximizing smolt tagging operational efficiency. Will assist in all aspects of field operations, including safe operation of riverboats and all other equipment, tagging, data collection, data recording, and general field camp duties including keeping camp and field equipment neat and orderly. Responsible for fish handling to prevent mortalities or injuries.

Tory Rhoads, FWT II. This position is responsible for assisting in all aspects of smolt field operations, including safe operation of riverboats and all other equipment, tagging, data

collection and general field camp duties including keeping camp and field equipment neat and orderly. Will be clipper or tagger in tagging shed as needed.

Evan Fritz, FWT II. This position is responsible for assisting in all aspects of smolt field operations, including safe operation of riverboats and all other equipment, tagging, data collection and general field camp duties including keeping camp and field equipment neat and orderly. Will be clipper or tagger in tagging shed as needed.

Mike Lafollette, Fishery Biologist I. This position serves as crew leader on the Canyon Island fish wheel and set gillnet tagging operations for adult coho salmon, and collection and recording of all associated biological and catch-effort data, including CWT recovery. Ensures that the operational plan is followed to the extent possible, and implements inseason changes as authorized. Determines work schedules and assigns tasks to fish wheel crew members. Tags fish, collects samples, and records data according to operational plan. Monitors crew performance and corrects or trains the crew as needed. Ensures pertinent portions of state SOP, such as safety and time reporting, are followed. Maintains near-daily contact with Williams for safety, data, and logistical needs.

Michael Enders, FWT III. This position is responsible for being second in charge of fish wheel and set gillnet operations for tagging and sampling adult salmon, and assists in all aspects of the project. Will be under direct supervision of the Canyon Island crew leader. Will consult with Williams regarding the efficiency of work and will provide input on changes necessary to improve operations.

Zane Chapman, FWT II. This position is responsible for working on the fish wheels and set gillnetting for tagging and sampling adult salmon, and assists in all aspects of the project. Will be under direct supervision of the Canyon Island crew leader. Will consult with Williams regarding the efficiency of work and will provide input on changes necessary to improve operations.

APPENDIX A

On the surface, Petersen's estimator for closed populations seems appropriate for estimating smolt abundance of coho salmon in the context of using coded wire tags (CWTs). A sample of smolts is marked and tagged one year, and a sample of adults is inspected for marks in the following year. During the year at sea the population is open to mortality, but because of their life history, the population is closed to recruitment. If all other conditions are met, the mark-recapture experiment should provide an asymptotically accurate estimate of the abundance of smolts.

One condition that is not met for the experiment on the Taku River from 2001–2002 is that each smolt must have an equal probability of being marked or inspected for marks regardless of their size. Smaller smolt were less likely to be captured in 2001 than were larger smolt. Since smaller smolt suffered a higher mortality rate than did larger smolt, smaller smolt also had less of a chance of being recaptured as adults. Ignoring these circumstances produces an estimate of abundance that is biased low.

Under these circumstances, abundance of coho salmon smolt can be estimated accurately using a weighted variant of Chapman's modification of Petersen's closed-population estimator:

$$\hat{N} = \frac{(\hat{A}M_1 + M_2 + 1)(C + 1)}{\hat{A}(R_1 + \hat{\pi}R_3) + R_2 + (1 - \hat{\pi})R_3 + 1} - 1 \quad (\text{A1.1})$$

where M is the number of smolts marked by size group (1 = smaller 75–85 mm FL, 2 = larger >85 mm FL) in 2001, C the number of adults in 2002 inspected for marks, R the subset of C with marks representing a size group of smolts (3 = group unknown), A is the ratio of the catchability coefficients for larger (>85 mm FL) to smaller (\leq 85 mm FL) smolt in 2001, and π is the fraction of adults in 2002 that were smolts 70–85 mm FL in 2001. The estimate A is used to adjust for differences in catchability in 2001 such that $A > 1$, when larger smolt are more catchable and < 1 when larger smolt are less catchable. Because some recaptured fish are not sacrificed to find tags or some marked adults do not contain tags, π is used to assign recaptured fish of unknown pedigree to the appropriate smolt size group. An estimate of π is:

$$\hat{\pi} = \frac{T_1}{T_1 + T_2} \quad (\text{A1.2})$$

where T is the number of all tags representing a smolt size group recovered or recaptured from adult salmon regardless of how or where recovered or recaptured.

Evidence for smolts not having equal probability of being marked or inspected for marks regardless of size can be found in the recovery rates of CWTs. Recovery of tags in 2002 from both

smolt groups indicates that smolt in the larger-size group survived about 54% better than did smaller smolt ($P < 0.0001$, $\chi^2 = 20.1$, $df = 1$):

Smolt size group	M	T	Recovery rate
Smaller	23,285	163	0.0070215
Larger	27,250	294	0.1078899

Vincent-Lang (1993) has shown that coho salmon smolts marked as in this project and handled competently suffer no detectable mortality from the experience. Also, there is no reason to believe that capture rates for adults is influenced by the code on a tag imbedded deep within its cartilage. For these reasons, the differences in recovery rates is most likely due to natural differences in survival rates. This difference means that smolts in the smaller-size group were less likely to be inspected for marks as adults than larger smolts.

Further calculations based on estimates of relative age composition of smolts and adults show that catchability of smolt in the larger-size group was about seven and a half times greater than the catchability of smaller smolt in 2001. If \hat{p} is the estimated fraction of all adults that are of age 1-freshwater, if $\hat{\phi}_1$ is the estimated fraction of smolt in the smaller-size group that were age 1-freshwater, and if $\hat{\phi}_2$ is the estimated fraction of smolt in the larger-size group that were age 1-freshwater, an estimate of the ratio of catchability coefficients for larger to smaller smolt is:

$$\hat{A} = \frac{T_2(\hat{\phi}_2 - \hat{p})}{T_1(\hat{p} - \hat{\phi}_1)} \quad (\text{A1.3})$$

(see Appendix Addendum A1.1 for derivation of eq. A1.3). From Appendix Table A1.1, $\hat{\phi}_1 = 228/242 = 0.9421$ and $\hat{\phi}_2 = 129/284 = 0.4542$. Of the 1,112 adults sampled at Canyon Island in 2002, 943 were age 1.1, making $\hat{p} = 943/1112 = 0.8480$. Given that $T_1 = 163$ and $T_2 = 294$ in 2002, $\hat{A} = 7.55$. Simulations (see below) indicate that this estimated rate is statistically different than 1.

Plugging statistics given above into eq. A1.1 and noting that $\hat{\pi} = 163/(163+294) = 0.357$, estimated abundance is:

$$2,718,816 = \frac{[(7.55)(23,285 + 27,250 + 1)][3,765 + 1]}{[(7.55(16 + \{0.357\}40) + 26 + \{1 - 0.357\}40) + 1]} - 1$$

Appendix Table A1.1.–Age composition of coho salmon smolt marked with coded wire and sampled for age in the Taku River in 2001.

	Age-1.1	Age-2.1	Total
Small	228	14	242
Large	129	155	284
Total	357	169	526

with $R_1 = 16$, $R_2 = 16$, $R_3 = 40$, and $C = 3,765$. The pooled estimate of abundance from the standard modification of Petersen’s estimator is 2,292,994, about 16% less.

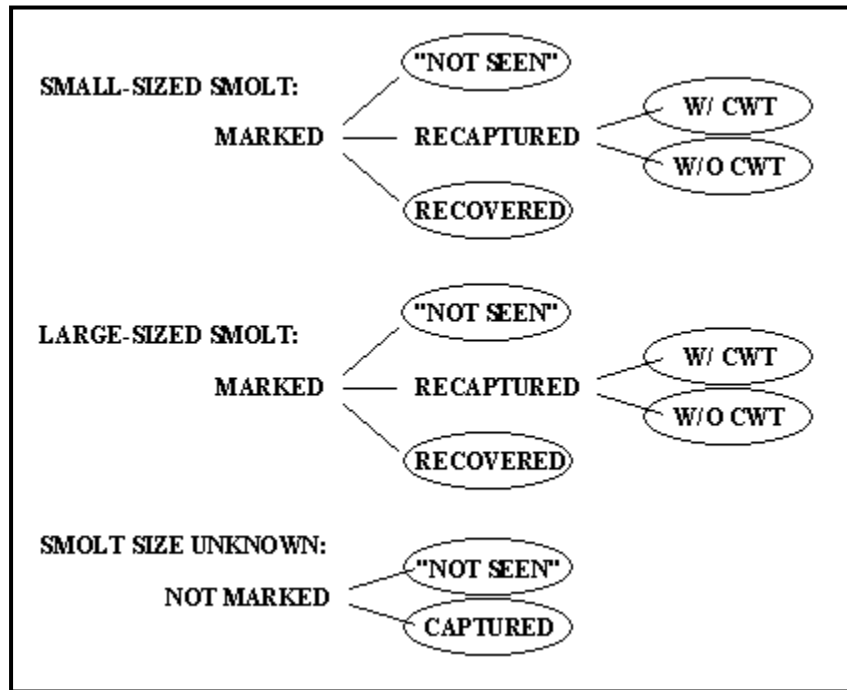

Variance and relative statistical bias in the estimator (eq. A1.1) was estimated with bootstrap procedures described in general by Buckland and Garthwaite (1991). Each bootstrap sample was drawn randomly with replacement from the capture histories of the \hat{N} smolt in the “virtual” population (Appendix Figure A1.1). From the bootstrap sample a new estimate of smolt abundance \hat{N}' was calculated. Then the process was repeated two hundred times to create the frequency distribution $\hat{F}'(\hat{N}')$. At the end of the iterations, the following statistics were calculated:

$$\bar{N}' = \frac{\sum_{b=1}^{200} \hat{N}'_{(b)}}{200} \quad (\text{A1.4a})$$

$$\text{var}(\hat{N}) = \frac{\sum_{b=1}^{200} (\hat{N}'_{(b)} - \bar{N}')^2}{200 - 1} \quad (\text{A1.4b})$$

$$\text{Estimated Relative Bias} = \frac{\bar{N}' - \hat{N}}{\hat{N}} (100) \quad (\text{A1.4c})$$

The 10 capture histories are provided in Appendix Table A1.2. Bootstrap estimates $\hat{\phi}'_1$ were obtained from a binomial distribution with parameters $M'_1/96$ and $\hat{\phi}_1$ (about 1 of every 96 captured smolt were sampled to determine age in 2001); estimates $\hat{\phi}'_2$ were estimated in the same manner. Bootstrap estimates \hat{p}' were obtained from a binomial distribution with parameters 1112 and \hat{p} .

Appendix Figure A1.1.–Capture histories (in ovals) concerning smolts in the population emigrating from the Taku River in 2001.

Results of the bootstraps simulations are as follows. The bootstrap estimate $\bar{N}' = 2,770,138$ indicating an estimate of relative statistical bias in \hat{N} less than 2%. The bootstrap estimate for the standard error of \hat{N} is 364,867 for a CV just over 13.4%. Simulated estimates of \hat{A} had a low of 4.069, a standard error of 2.195, and indicated a relative bias in \hat{A} of just over 29%. The BASIC program SMLTTAKU.BAS was used to conduct the simulations.

Appendix Table A1.2.–Relationships among history variables, capture histories, and model variables in bootstrap simulations.

Program Variable	Capture History	Model Variables	Values
n(1)	Not marked, not seen	$\hat{N} - M_1 - M_2 - C + R_1 + R_2 + R_3$	
n(2)	Marked, not seen - Smaller Smolt	$M_1 - T_1$	$23,250 - 163 = 23,122$
n(3)	" " - Larger Smolt	$M_2 - T_2$	$23,285 - 294 = 26,956$
n(4)	Marked, recaptured - Smaller Smolt w/ CWT	R_1	16
n(5)	" " - Larger Smolt w/ CWT	R_2	26
n(6)	" " - Smaller Smolt w/o CWT	$\hat{\pi} R_3$	$0.357(40) = 14$
n(7)	" " - Larger Smolt w/o CWT	$(1 - \hat{\pi}) R_3$	$(1 - 0.357)40 = 26$
n(8)	Marked, recovered - Smaller Smolt	$T_1 - R_1 - \hat{\pi} R_3$	$163 - 16 - 14 = 133$
n(9)	" " - Larger Smolt	$T_2 - R_2 - (1 - \hat{\pi}) R_3$	$294 - 26 - 26 = 242$
n(10)	Not Marked, captured	$C - R_1 - R_2 - R_3$	$3765 - 16 - 26 - 40 = 3683$

Appendix Addendum A1.1–Estimation of the ratio of catchabilities

The fraction p of adults with 1-freshwater age can be expressed as:

$$p = \frac{N_1 \phi_1 S_1 + N_2 \phi_2 S_2}{N_1 S_1 + N_2 S_2} = \frac{N_1 \phi_1 S_1 + N_2 \phi_2 B S_1}{N_1 S_1 + N_2 B S_1} = \frac{N_1 \phi_1 + N_2 \phi_2 B}{N_1 + N_2 B}$$

where N is smolt number by smolt size group, S their survival rate, ϕ the fraction of the smolt group comprised of smolt age 1-freshwater, and B is the ratio of survival rates S_2/S_1 . This relationship simplifies to:

$$\frac{N_1}{N_2} = \frac{B(\phi_2 - p)}{(p - \phi_1)}$$

If α is the capture rate of smolts, then $M_1 = \alpha_1 N_1$ and $M_2 = \alpha_2 N_2$, and:

$$\frac{N_1}{N_2} = \frac{M_1}{M_2} \frac{\alpha_2}{\alpha_1} = \frac{B(\phi_2 - p)}{(p - \phi_1)}$$

If A is the ratio of catchability for the two groups of smolts, then $A = \alpha_2 / \alpha_1$ since fishing effort by definition is equal for both groups. Substitution creates:

$$A = \frac{M_2 B(\phi_2 - p)}{M_1 (p - \phi_1)}$$

A naïve estimate of A is therefore:

$$\hat{A} = \frac{M_2 \hat{B}(\hat{\phi}_2 - \hat{p})}{M_1 (\hat{p} - \hat{\phi}_1)}$$

Noting that the estimate for the ratio of survival rates is:

$$\hat{B} = \frac{T_2}{M_2} \frac{M_1}{T_1}$$

A simpler estimate for A is:

$$\hat{A} = \frac{T_2(\hat{\phi}_2 - \hat{p})}{T_1(\hat{p} - \hat{\phi}_1)}$$

Appendix A 2.–Statistics from 2014 used to link the number of coho salmon smolt to tag each year with the ultimate relative precision of the estimated harvest from adults returning to the Taku River in 2015.

$\phi = 0.24$ (average all fisheries); $\theta = 0.0071$ (x 926,067 smolt corresponds to 6,856 smolt tagged); $G(\theta^{-1}) = .002$

Appendix A 3.–Detection of size and/or sex selective sampling during a two-sample mark recapture experiment and its effects on estimation of population size and population composition.

Size selective sampling: The Kolmogorov-Smirnov two sample test (Conover 1980) is used to detect significant evidence that size selective sampling occurred during the first and/or second sampling events. The second sampling event is evaluated by comparing the length frequency distribution of all fish marked during the first event (M) with that of marked fish recaptured during the second event (R) by using the null test hypothesis of no difference. The first sampling event is evaluated by comparing the length frequency distribution of all fish inspected for marks during the second event (C) with that of R. A third test that compares M and C is then conducted and used to evaluate the results of the first two tests when sample sizes are small. Guidelines for small sample sizes are <30 for R and <100 for M or C.

Sex selective sampling: Contingency table analysis (Chi²-test) is generally used to detect significant evidence that sex selective sampling occurred during the first and/or second sampling events. The counts of observed males to females are compared between M&R, C&R, and M&C using the null hypothesis that the probability that a sampled fish is male or female is independent of sample. If the proportions by gender are estimated for a sample (usually C), rather than observed for all fish in the sample, contingency table analysis is not appropriate and the proportions of females (or males) are then compared between samples using a two sample test (e.g. Student's t-test).

M vs. R	C vs. R	M vs. C
<i>Case I:</i>		
Fail to reject H ₀	Fail to reject H ₀	Fail to reject H ₀
There is no size/sex selectivity detected during either sampling event.		
<i>Case II:</i>		
Reject H ₀	Fail to reject H ₀	Reject H ₀
There is no size/sex selectivity detected during the first event but there is during the second event sampling.		
<i>Case III:</i>		
Fail to reject H ₀	Reject H ₀	Reject H ₀
There is no size/sex selectivity detected during the second event but there is during the first event sampling.		
<i>Case IV:</i>		
Reject H ₀	Reject H ₀	Either result possible
There is size/sex selectivity detected during both the first and second sampling events.		
<i>Evaluation Required:</i>		
Fail to reject H ₀	Fail to reject H ₀	Reject H ₀
Sample sizes and powers of tests must be considered:		

A. If sample sizes for M vs. R and C vs. R tests are not small and sample sizes for M vs. C test are very large, the M vs. C test is likely detecting small differences which have little potential to result in bias during estimation. *Case I* is appropriate.

B. If a) sample sizes for M vs. R are small, b) the M vs. R p-value is not large (~0.20 or less), and c) the C vs. R sample sizes are not small and/or the C vs. R p-value is fairly large (~0.30 or more), the rejection of the null in the M vs. C test was likely the result of size/sex selectivity during the second event which the M vs. R test was not powerful enough to detect. *Case I* may be considered but *Case II* is the recommended, conservative interpretation.

C. If a) sample sizes for C vs. R are small, b) the C vs. R p-value is not large (~0.20 or less), and c) the M vs. R sample sizes are not small and/or the M vs. R p-value is fairly large (~0.30 or more), the rejection of the null in the M vs. C test was likely the result of size/sex selectivity during the first event which the C vs. R test was not

powerful enough to detect. *Case I* may be considered but *Case III* is the recommended, conservative interpretation.

D. If a) sample sizes for C vs. R and M vs. R are both small, and b) both the C vs. R and M vs. R p-values are not large (~0.20 or less), the rejection of the null in the M vs. C test may be the result of size/sex selectivity during both events which the C vs. R and M vs. R tests were not powerful enough to detect. *Cases I, II, or III* may be considered but *Case IV* is the recommended, conservative interpretation.

Case I. Abundance is calculated using a Petersen-type model from the entire data set without stratification. Composition parameters may be estimated after pooling length, sex, and age data from both sampling events.

Case II. Abundance is calculated using a Petersen-type model from the entire data set without stratification. Composition parameters may be estimated using length, sex, and age data from the first sampling event without stratification. If composition is estimated from second event data or after pooling both sampling events, data must first be stratified to eliminate variability in capture probability (detected by the M vs. R test) within strata. Composition parameters are estimated within strata, and abundance for each stratum needs to be estimated using a Petersen-type formula. Overall composition parameters are estimated by combining stratum estimates weighted by estimated stratum abundance according to the formulae below.

Case III. Abundance is calculated using a Petersen-type model from the entire data set without stratification. Composition parameters may be estimated using length, sex, and age data from the second sampling event without stratification. If composition is estimated from first event data or after pooling both sampling events, data must first be stratified to eliminate variability in capture probability (detected by the C vs. R test) within strata. Composition parameters are estimated within strata, and abundance for each stratum needs to be estimated using a Petersen-type formula. Overall composition parameters are estimated by combining stratum estimates weighted by estimated stratum abundance according to the formulae below.

Case IV. Data must be stratified to eliminate variability in capture probability within strata for at least one or both sampling events. Abundance is calculated using a Petersen-type model for each stratum, and estimates are summed across strata to estimate overall abundance. Composition parameters may be estimated within the strata as determined above, but only using data from sampling events where stratification has eliminated variability in capture probabilities within strata. If data from both sampling events are to be used, further stratification may be necessary to meet the condition of capture homogeneity within strata for both events. Overall composition parameters are estimated by combining stratum estimates weighted by estimated stratum abundance.

If stratification by sex or length is necessary prior to estimating composition parameters, then an overall composition parameters (p_k) is estimated by combining within stratum composition estimates using:

$$\hat{p}_k = \sum_{i=1}^j \frac{\hat{N}_i}{\hat{N}_\Sigma} \hat{p}_{ik} ; \text{ and,} \quad (1)$$

$$\hat{V}[\hat{p}_k] \approx \frac{1}{\hat{N}_\Sigma^2} \sum_{i=1}^j \left(\hat{N}_i^2 \hat{V}[\hat{p}_{ik}] + (\hat{p}_{ik} - \hat{p}_k)^2 \hat{V}[\hat{N}_i] \right). \quad (2)$$

where:

- j = the number of sex/size strata;
- \hat{p}_{ik} = the estimated proportion of fish that were age or size k among fish in stratum i ;
- \hat{N}_i = the estimated abundance in stratum i ; and,
- \hat{N}_Σ = sum of the \hat{N}_i across strata.

Appendix A 4.–Tests of consistency for the Petersen estimator (from Seber 1982, page 438).

Tests of consistency for petersen estimator

Of the following conditions, at least one must be fulfilled to meet assumptions of a Petersen estimator:

1. Marked fish mix completely with unmarked fish between events;
2. Every fish has an equal probability of being captured and marked during event 1; or,
3. Every fish has an equal probability of being captured and examined during event 2.

To evaluate these three assumptions, the chi-square statistic will be used to examine the following contingency tables as recommended by Seber (1982). At least one null hypothesis needs to be accepted for assumptions of the Petersen model (Bailey 1951, 1952; Chapman 1951) to be valid. If all three tests are rejected, a temporally or geographically stratified estimator (Darroch 1961) should be used to estimate abundance.

I.-Test For Complete Mixing^a

Area/Time Where Marked	Area/Time Where Recaptured				Not Recaptured (n_1-m_2)
	1	2	...	t	
1					
2					
...					
s					

II.-Test For Equal Probability of capture during the first event^b

	Area/Time Where Examined			
	1	2	...	t
Marked (m_2)				
Unmarked (n_2-m_2)				

III.-Test for equal probability of capture during the second event^c

	Area/Time Where Marked			
	1	2	...	s
Recaptured (m_2)				
Not Recaptured (n_1-m_2)				

^a This tests the hypothesis that movement probabilities (θ) from time or area i ($i = 1, 2, \dots, s$) to section j ($j = 1, 2, \dots, t$) are the same among sections: $H_0: \theta_{ij} = \theta_j$.

^b This tests the hypothesis of homogeneity on the columns of the 2-by-t contingency table with respect to the marked to unmarked ratio among time or area designations: $H_0: \sum_i a_i \theta_{ij} = k U_j$, where k = total marks released/total unmarked in the population, U_j = total unmarked fish in stratum j at the time of sampling, and a_i = number of marked fish released in stratum i .

^c This tests the hypothesis of homogeneity on the columns of this 2-by-s contingency table with respect to recapture probabilities among time or area designations: $H_0: \sum_j \theta_{ij} p_j = d$, where p_j is the probability of capturing a fish in section j during the second event, and d is a constant.

Appendix B 2.—Data form to record daily CWT tagging results.

CWT DAILY TAGGING, ADF&G Division of Sport Fish

Location: Taku River

Species: Coho**Year: 2016**

Date: _____

Tag code: _____

Machine Serial Number: _____

a. Number of fish tagged _____

b. Post tagging mortalities

c. Total tagged fish released (a-b)

Recaptures:

d. Number with CWTs

e. Total number of recaptures

24 hour tag retention:

f. Number with CWTs

g. Total number tested

h. Short-term retention % (f/g)

i. Adjusted tagged and released (h*c)

Cumulative tagged and released:

Comments
